U.S. Patent and Trademark Office PTOL-326 (Rev. 7-05)

Art Unit: 2859

DETAILED ACTION

Claim Rejections - 35 USC § 102

1. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless -

- (b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.
- 2. Claims 1-4, 8-9, and 11-12 are rejected under 35 U.S.C. 102(b) as being anticipated by Yamashita et al. (US 2001/0022515).

Regarding claim 1, Yamashita et al. discuss an MRI system (Par 1) comprising an examination volume and a main magnet system for generating a magnetic field having a mail field portion with a substantially constant magnetic field strength in the examination volume (par 73), a gradient system for generating gradients of the main field portion (par 74), and a damping member (par 82—the cable 2042 supplying current to the gradient coils may be read as a "damping member"; alternatively the cable mount plate 2016 may be read as a damping member) which is mounted to a part of the MRI system susceptible to vibrations relative to the magnetic field during operation (par 81, 82, 85; the cable is mounted to the gradient coils, which are susceptible to vibration; alternatively, the plate 2016 is mounted to the cable which is itself susceptible to vibration; the plate is also mounted indirectly to the gradient coils (via the cable), and finally the plate is mounted to the housing of the main magnet system, which is susceptible to vibration), said damping member comprising an electrically conductive member which is present in the magnetic field and in which eddy currents are generated

Art Unit: 2859

as a result of vibrations (par 82-83, Figs 1, 4—the cable and the mount plate 2016 are both conductive, and are both present in the magnetic field, and thus support eddy currents as a result of their vibrations) wherein the conductive member is arranged in a secondary portion of the magnetic field at a distance from the main field portion, the secondary portion having a field strength which differs by more than 25% from the field strength of the mail field portion (the cables and the cable mount plate are both at least partially located outside of the bore of the magnet (fig 1, 4), and thus in a region of much lower magnetic field (e.g., as is known in the art, the magnetic field on axis at the end of a solenoid is half what it is in the center (the main or imaging region), and further decreases off axis. Thus, the magnetic field at the location of the cable and cable mount plate is substantially less than 50% of the field in the main field region.)).

Regarding claim 2, the magnetic field strength in the secondary portion differs by more than 50% from the magnetic field strength in the main field portion, as discussed above regarding claim 1.

Regarding claim 3, the conductive members are located in a stray field portion of the magnetic field (Fig 1, 4—they are located outside the bore).

Regarding claim 4, the conducting member is mounted to the gradient system (fig 1, 4; pars 81-85—the cable is mounted directly to the gradient coils; alternatively the cable mount plate could be said to be mounted indirectly (via the cable) to the gradient coils).

Regarding claim 8, cable mount plate 2016 and cable 2042 are mounted to a housing of the main magnet system 2001 (fig 1, 4).

Art Unit: 2859

Regarding claim 9, the main magnet of Yamashita et al. is substantially circular cylindrical (fig 1, 4) wherein the gradient magnet system surrounds the examination volume and the main magnet system surrounds the gradient system (par 74, figs 1,4), the conductive member being mounted to an annular end wall of the housing of the main magnet system (cable mount plate **2016** and cable **2042** are mounted to an annular end wall of the housing of the main magnet system **2001** (fig 1, 4).).

Regarding claim 11, the conductive member is mounted to a support member which supports the housing of the main magnet system (par 92-93—the cable (and indirectly the cable mount plate) is mounted to the supporting base **2015**).

Regarding claim 12, the conductive member **2016** is a substantially flat plate (fig 1, 4).

3. Claims 1-3, 8, and 10-11 are rejected under 35 U.S.C. 102(b) as being anticipated by Radziun et al. (US 6,375,147).

Regarding claim 1, Radziun et al. discuss an MRI system (col 1, lines 5-17) comprising an examination volume **12**, a main magnet system for generating a magnetic field having a main field portion with a substantially constant magnetic field strength in the portion (col 3, lines 39-45), and a damping member **14** which is mounted to a part of the MRI system susceptible to vibrations relative to the magnetic field during operation (the damping member is mounted to a housing of the main magnet system, which is susceptible to vibrations, fig 1), said damping member comprising a conductive member (member **14** is metal, col 3, lines 46-49) and in which eddy currents are

Art Unit: 2859

generated as a result of said vibrations (the metal object **14** is conductive and is present in the fringe field of the magnet, and will vibrate as a result of its being mounted to the housing. As such it will support eddy currents.), wherein the conductive member is arranged in a secondary portion of the magnetic field at a distance from the main portion, the secondary portion having a magnetic field strength which differs by more than 25% from the main field portion (object **14** is located in a fringe field region, which has a field different from the main field by substantially more than 50%, as discussed above regarding claim 1).

Regarding claim 2, the magnetic field strength in the secondary portion differs by more than 50% from the magnetic field strength in the main field portion, as discussed above regarding claim 1.

Regarding claim 3, the conductive member **14** is located in a stray field region (fig 1).

Regarding claim 8, the conductive member **14** is mounted to a housing of the main magnet system (col 3, lines 46-49, fig 1).

Regarding claim 10, the main magnet of Radzuin et al. is substantially circular cylindrical (fig 1) wherein the gradient magnet system surrounds the examination volume and the main magnet system surrounds the gradient system (col 3, lines 39-57), the conductive member being mounted to a portion of the cylindrical outer wall of the housing of the main magnetic system adjacent to an annular end wall (Fig 1).

Regarding claim 11, the conductive member is mounted to a support member **46** which supports the housing of the main magnet system (fig 1).

Art Unit: 2859

Claims 1-5 are rejected under 35 U.S.C. 102(b) as being anticipated by Ham (US 4. 6,147,494). Ham discusses a MRI system (col 1, lines 7-19) comprising an examination volume 29, a main magnet system for generating a magnetic field having a main field portion with a substantially constant magnetic field strength in the examination volume (col 5, lines 20-22), a gradient magnet system for generating gradients of the main field portion (col 5, lines 22-25), and a damping member which is mounted to a part of the MRI system susceptible to vibrations, said damping member comprising an electrically conductive member which is present in the magnetic field and in which eddy currents are generated as a result of said vibrations (The gradient coils are connected to gradient power supply 7 by a conductive member as seen in Fig 1. This conductive member may be read as a "damping member" since it is conductive, will vibrate due to some extent due to its connection to the gradient coils (which are susceptible to vibration) and runs through regions of various strength of magnetic field and thus will have a small effect of damping the vibrations in accordance with Lenz's law when eddy currents are induced in it)), wherein the conductive member is arranged in a secondary field portion at a distance from the main field portion, the secondary field portion having a magnetic field strength which differs by more than 25% from the magnetic field strength of the main field portion (the conductive member in question runs outside the magnet to the gradient power supply, which is in a region of very low magnetic field since it contains magnets and currents not compatible with high magnetic fields; Fig 1).

Art Unit: 2859

Regarding claims 2 and 3, the conductive member is arranged in a region of very low magnetic field in the stray field region as discussed above regarding claim 1.

Regarding claim 4, the conductive member is mounted to the gradient coil system (fig 1).

Regarding claim 5, the main magnet of Ham comprises a first substantially rotationally symmetric portion and a second substantially symmetric portion at a distance from the first portion, wherein the examination volume is present between the first and second portion (Fig 2, 3; col 5 line 55-65), and wherein the gradient magnet system comprises a first and second portions arranged respectively in a central cavity of the first portion of the main magnet system and in a central cavity of the second portion of the main magnet system (gradient coils 73 and 77, and their counterparts in the vicinity of the other pole of the main magnet system; fig 2, 3), a first and second conductive member being mounted, respectively, to the first portion of the gradient magnet system and to the second portion of the gradient magnet system, and being arranged, respectively, in a portion of the central cavity of the first portion of the main magnet system remote from the examination volume and in a second portion of the main magnet system remote from the examination volume (col 5, lines 20-27; while not shown in Figs 2 and 3, the gradient coils shown inherently have power cables attached to them (as those seen in fig 1), which run to regions of low magnetic field for connection to a power supply 7.).

Art Unit: 2859

Allowable Subject Matter

5. Claims 6 and 7 are objected to as being dependent upon a rejected base claim, but would be allowable if rewritten in independent form including all of the limitations of the base claim and any intervening claims.

The following is a statement of reasons for the indication of allowable subject matter: The prior art of record does not teach or fairly suggest an MRI system comprising conductive damping members which comprise either cylindrical metal plates concentrically arranged relative to the first and second portions of the main magnetic field, or a conductive metal winding having winding portions extending substantially parallel to a central axis of the first and second portions of the main magnet system, in combination with the other limitations of the claims.

Conclusion

6. The prior art made of record and not relied upon is considered pertinent to applicant's disclosure. Westphal (US 6,501,275) and Westphal et al (US 2002/0140428) discuss the sort of acoustic damping (using conductors attached to the gradient coils and Lenz's law) described by Applicant, but the damping members are located in the main field region. Sellers (US 5,661,399) discusses a different, but related, sort of damping method.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to Jeremiah Shipman whose telephone number is
